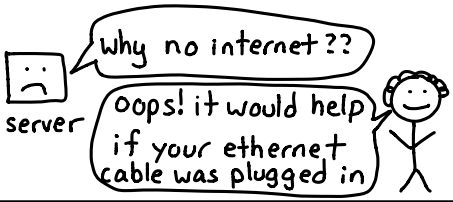
Linux only tool	BSD/Mac equivalent
ip	ifconfig, route
tc	dummynet (?) (BSD)
ss	netstat
iptables	pf (BSD)
ethtool	ifconfig, kind of (?)

ethtool

ethtool is for people who need to manage physical networks



ethtool eth0

name of network interface

this tells you:
- is it even connected? ("link detected")
- speed
- lots more

--show-offload
--offload

your network card can do a lot for you! Like computing checksums. This is called "offloading".

This lets you see/change configured offloads.

--identify INTERFACE

blink the light on the ethernet port. good if you have multiple ports! and cute♥

-s

change speed/duplex/other settings of an interface

```
$ ethtool -s eth0 speed 100
```

iw dev wlan0 link

ethtool is mostly for Ethernet.

To see the speed (and more) of a wireless connection, use iw.

-S INTERFACE

show statistics like bytes sent. works for wifi interfaces too.

-i INTERFACE

show firmware info

conntrack

conntrack

not a command line tool:
it's a Linux kernel system for tracking TCP /UDP connections.

It's a kernel module called nf_conntrack

conntrack is used for:

- NAT (in a router!)
- firewalls (eg only allow outbound connections)

You control it with iptables rules.

conntrack has a table of every connection

Each entry contains:

- src + dest IP
- src + dest ports
- the connection state (eg TIME_WAIT)

how to enable conntrack

enable:

```
$ sudo modprobe nf_conntrack
```

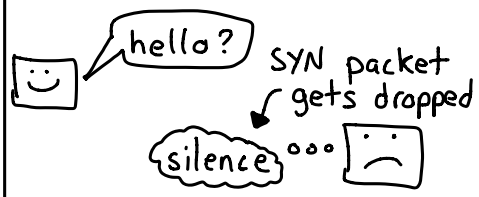
check if it's enabled:

```
$ lsmod | grep conntrack
```

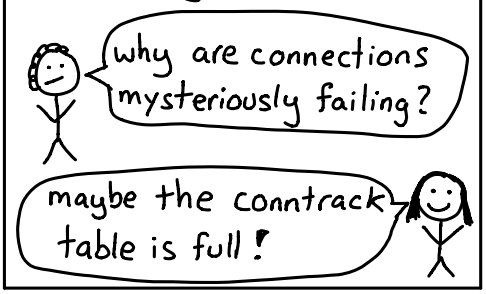
change table size with the sysctl

```
net.netfilter.nf_conntrack_max
```

if the conntrack table gets full, no new connections can start



moral: be careful about enabling conntrack!



♥ Table of contents ♥

dig

dig makes DNS queries!

```
$ dig google.com
```

answers have 5 parts:

```
query: google.com
TTL: 22
class: IN  <- (for "internet") ignore this
record type: A
record value: 172.217.13.110
```

dig TYPE domain.com

this lets you choose which DNS record to query for!

types to try: NS (default) MX TXT CNAME A

dig @8.8.8.8 domain

↖ Google DNS server

dig @server lets you pick which DNS server to query! Useful when your system DNS is misbehaving

dig +trace domain

traces how the domain gets resolved, starting at the root nameservers

if you just updated DNS, dig +trace should show the new record

dig -x 172.217.13.174

makes a reverse DNS query - find which domain resolves to an IP! Same as

```
dig ptr 174.13.217.172.in-addr.arpa
```

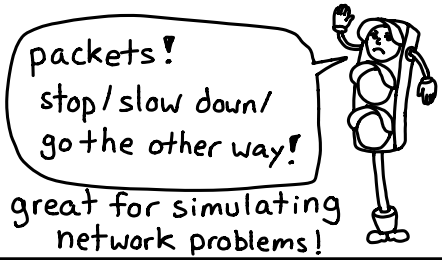
dig +short domain

Usually dig prints lots of output! With +short, it just prints the DNS record

tc

tc

is for "traffic control"



great for simulating network problems!

make your internet slow

```
$ sudo tc qdisc add dev
  wlp3s0 root netem
  delay 500ms
```

<- delay packets by 500ms

and fast again.

```
$ sudo tc qdisc del dev
  wlp3s0 root netem
```

netem rules

netem ("network emulator") is a part of tc that lets you:

drop, duplicate, delay, corrupt

packets. See the man page:

```
$ man netem
```

make your brother's internet slow

Have a Linux router? You can configure tc on it to make your brother's internet slower than yours

google: "tc QoS" for a start

show current tc settings

```
$ tc qdisc show
$ tc class show dev DEV
$ tc filter show dev DEV
```

iptables

iptables lets you create rules to match network packets and accept/drop/modify them

It's used for firewalls and NAT

tables have chains chains have rules

tables: filter, nat, mangle, raw, security

chains: INPUT, FORWARD, PREROUTING, etc

rules: like `-s 10.0.0.0/8 -j DROP`

iptables-save

This prints out all iptables rules. You can restore them with `iptables-restore`

but it's also the easiest way to view all rules!

-j TARGET

Every iptables rule has a target (what to do with matching packets). Options:

- ACCEPT, DROP, RETURN
- the name of an iptables chain
- an extension (man iptables-extensions)

Popular: DNAT, LOG, MASQUERADE

tables have different chains

filter: INPUT, OUTPUT, FORWARD

mangle: INPUT, OUTPUT, FORWARD, PREROUTING, POSTROUTING

nat: OUTPUT, PREROUTING, POSTROUTING

It helps to know when packets get processed by a given table/chain (eg locally generated packets go through filter and OUTPUT)

you can match lots of packet attributes

-s: src ip

-p: tcp/udp

-d: dst ip

-i: network interface

-m: lots of things!

(bpf rules! cgroups! ICMP type! cpu! conntrack state! more!)

For more, run:

```
$ man iptables-extensions
```

ping & traceroute

ping checks if you can reach a host and how long the host took to reply

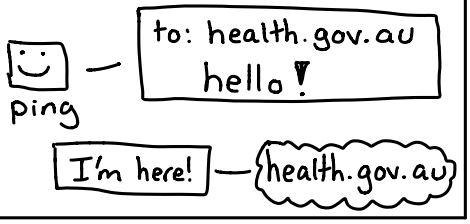
```
$ ping health.gov.au
```

output:

```
... time=253ms ...
```

Australia is 17,000 km from me. at the speed of light it's still far!

ping works by sending an ICMP packet and waiting for a reply



myth: if a host doesn't reply to ping, that means it's down

Some hosts never respond to ICMP packets. This is why traceroute shows "..." sometimes.

traceroute tells you the path a packet takes to get to a destination

example traceroute

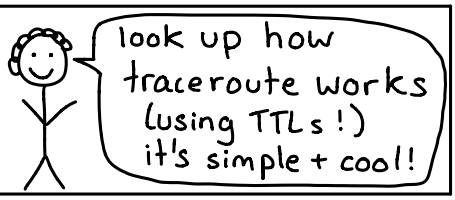
```
$ traceroute health.gov.au
1: 192.168.1.1 3ms          ← router
2: ...yul.ebox.ca 12 ms     ← ISP
                ...
8: NYC4.ALTER.NET 24 ms
9: SAC1.ALTER.NET 97 ms
16: health.gov.au 253ms
```

crossing the US takes time

here the packet crossed the USA! from NYC -> Sacramento!

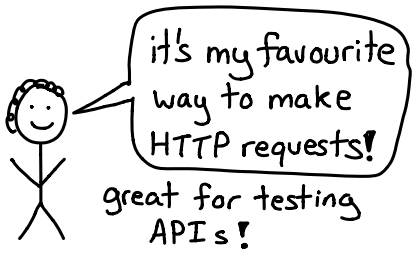
mtr

like traceroute, but nicer output! try it!



curl

curl



great for testing APIs!

```
$ curl wizardzines.com
```

-H

is for header

good for POST requests to JSON APIs:

```
-H "Content-Type: application/json"
```

allow compressed response:

```
-H "Accept-Encoding: gzip"
```

-L

follow 3xx redirects

--data

to POST data!

```
--data '{"name": "julia"}'

--data @filename.json
```

@ reads the data to send from a file

-i

show response headers

-I

show only response headers (makes a HEAD request)

-X POST

send a POST request instead of a GET (-X PUT etc works too)

-v

show request headers & more

-k

insecure: don't verify SSL certificates

--connect-to ::IP

send request to IP instead. (or hostname)

use before changing DNS to a new IP

★ copy as cURL ★

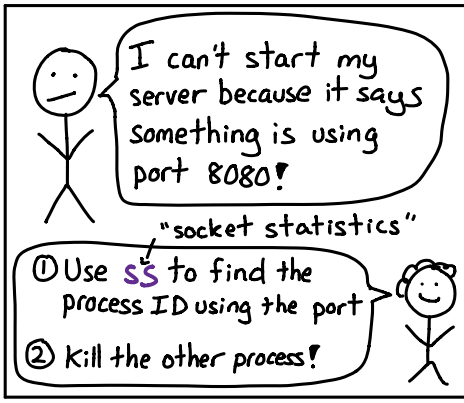
Have something in your browser you want to download from the command line?

In Firefox / Chrome / Safari:

Developer Tools
→ Network tab
→ right click on the request
→ copy as curl

(can have sensitive info in cookies!)

ss



★ tuna, please! ★

```
$ ss -tunapl
```

the 'a' here doesn't do anything

This is my favourite way to use ss! It shows all the running servers

-n

use numeric ports (80 not http)

-p

show PIDs using the socket

TONS of information

-i -m -o

which sockets ss shows

listening or connections?

default: connections
-l : listening
-a : both

(non-listening / established)

which protocols?

default: all
-t : TCP
-u : UDP
-x : unix domain sockets

netstat

netstat -tunapl and ss -tunapl do the same thing

netstat is older and more complicated. If you're learning now, I'd recommend ss!

ip

ip

Linux only

lets you view + change network configuration.

```
$ ip OBJECT COMMAND
```

OBJECT: addr, link, neigh, etc

COMMAND: add, show, delete, etc

ip addr list

shows ip addresses of your devices. Look for something like this:

```
2: eth0:
    link/ether 3c:97...
    inet 192.168.1.170/24
```

ip route list

displays the route table.

```
default via 192.168.1.1   (my router)
169.240.0.0/16 dev docker0
...
```

to see all route tables:

```
$ ip route list table all
```

Change your MAC address

good for cafés with time limits

```
$ ip link set wlan0 down
$ ip link set eth0 address
  3c:a9:f4:d1:00:32
$ ip link set wlan0 up
$ service network-manager
  restart
```

← or whatever you use

ip link

network devices! (like eth0)

ip neigh

view/edit the ARP table

ip xfrm

is for IPsec

ip route get IP

What route will packets with $IP take?

-- color

pretty colourful output!

-- brief

show a summary

nmap

nmap lets you explore a network

security people use it a lot!

find which hosts are up

```
$ nmap -sn 192.168.1.0/24
```

(my home network)

-sn means "ping scan" (not -s + -n, it's -sn)

just finds hosts by pinging every one, doesn't port scan

aggressive scan

```
nmap -v -A scanme.nmap.org
```

(-A: aggressive)

port, server version, even OS

-Pn

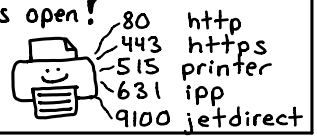
skip doing a ping scan and assume every host is up. good if hosts block ping (lots do!)

fast port scan

```
$ nmap -sS -F 192.168.1.0/24
```

just sends a SYN packet to check if each port is open.

I found out which ports my printer has open!



-F

scan less ports: just the most common ones

-T4 or -T5

scan faster by timing out more quickly

♡ check TLS version and ciphers ♡

check if your server still supports old TLS versions

```
$ nmap
  --script ssl-enum-ciphers
  -p 443 wizardzines.com
```

list all scripts with:

```
$ nmap --script-help '*'
```

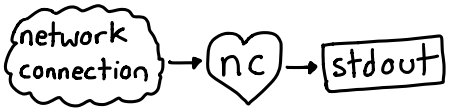
netcat

nc

lets you create TCP (or UDP) connections from the command line

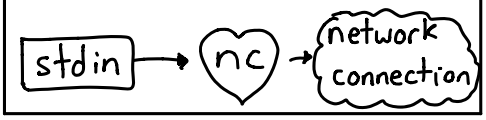
nc -l PORT

start a server! this listens on PORT and prints everything received



nc IP PORT

be a client! opens a TCP connection to IP:PORT.
(to send UDP use -u)



make HTTP requests by hand

```
$ printf 'GET / HTTP/
  1.1\r\nHost:
  example.com\r\n\r\n'
 | nc example.com 80
```

all one line

type in any weird HTTP request you want!

send files

want to send a 100 GB file to someone on the same wifi network? easy!

receiver:

```
$ nc -l 8080 > file
```

sender:

```
$ cat file.txt | nc YOUR_IP 8080
```

I ♥ this trick! It works even if you're disconnected from the internet!

ssh

♥ ssh keys ♥

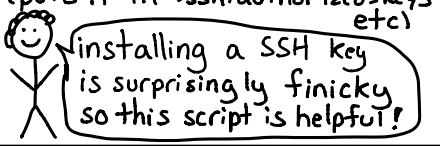
An ssh key is a secret key that lets you SSH to a machine

ssh-copy-id

This script installs your SSH key on a host (over SSH)

```
$ ssh-copy-id user@host
```

(puts it in .ssh/authorized_keys etc)



★ port forwarding ★

```
ssh user@host.com -NfL
3333:localhost:8888
```

local port ↑ ↑ remote port

Lets you view a remote server that's not on the internet in your browser.

just run 1 command

```
$ ssh user@host uname -a
```

runs this command & exits

~.

<Enter>~. closes the SSH connection. Useful if it's hanging!

.ssh/config

Lets you set, per host:

- username to use
- SSH key to use
- an alias!

so you can type `$ ssh ALIAS` instead of `ssh user@verylongdomain.com`

ssh-agent

remembers your SSH key passphrase so you don't have to keep typing it

mosh

ssh alternative: keeps the connection open if you disconnect + reconnect later

miscellaneous networking tools

stunnel
make a SSL proxy for an insecure server

hping3
make any TCP packet

wget
download files

aria2c
a fancier wget

rsync
sync files over SSH or locally

lsof
what ports are being used?

httpie
like curl but friendlier

iftop/nethogs/ntop/iptraf/nload
see what's using bandwidth

whois
is this domain registered?

ipcalc
easily see what 13.21.2.3/25 means

python3 -m http.server
serve files from a directory

nftables
new version of iptables

zenmap
GUI for nmap

p0f
identify OS of hosts connecting to you

openvpn wireguard
VPNs

tcpflow
capture and assemble TCP streams

sysctl
configure Linux kernel's network stack

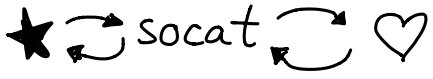
ab/iperf
benchmarking tools

links
a browser in your terminal

telnet
can help debug text network protocols

socat

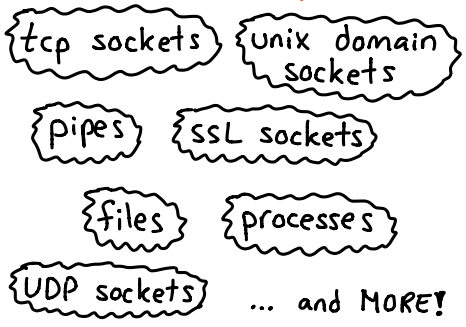
socat lets you proxy basically any 2 things



the basic syntax:

```
socat THING1 THING2
```

socat supports



order doesn't matter

```
socat THING1 THING2
```

is the same as

```
socat THING2 THING1
```

expose a unix domain socket on port 1337

```
socat TCP-LISTEN:1337
      UNIX-CONNECT:/path
```

proxy from local HTTP port to remote server

```
socat TCP-LISTEN:1337
      TCP:domain.com:80
```

-v

write all transferred data to stderr

tcpdump

10

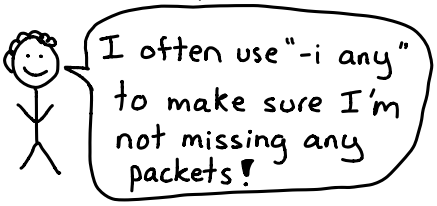
tcpdump lets you view network packets being sent & received

-n

don't try to resolve IP addresses / ports to DNS / port names. makes it run faster.

-i wlan0

Which network interface to capture packets on



-w file.pcap

Write packets to a file for later analysis with tcpdump / tshark / wireshark / another tool

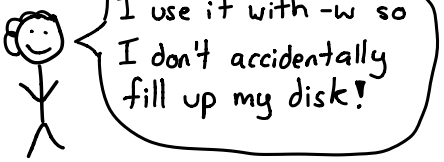
pcap is for "packet capture"

-A

print packet contents, not just headers. Nice if you want to quickly see what a few packets contain.

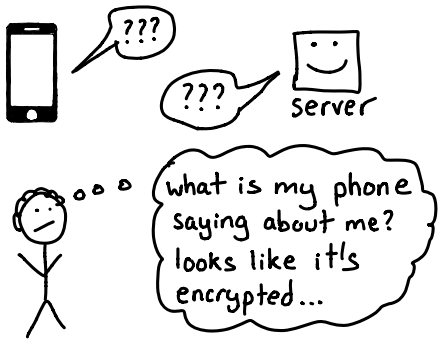
-c 100000

Only capture a limited count of packets



mitmproxy

15



mitmproxy can proxy connections from your laptop or phone and let you see the contents. It even works with encrypted connections!

how you use it

1. install mitmproxy root CA on your laptop / phone
2. run mitmweb (web UI version) on computer
3. tell the program / phone to proxy through mitmproxy

how it works

some apps pin a cert

makes mitmproxy not work, look up "trust killer" to get around that

script it in Python

modify requests / responses arbitrarily

other similar tools

(not all are free, though)

- charles proxy
- burp suite
- fiddler

openssl

openssl is a tool for doing ★SSL aka TLS things★

inspect certificates
create CSRs
sign certificates

It uses the OpenSSL library (or LibreSSL)

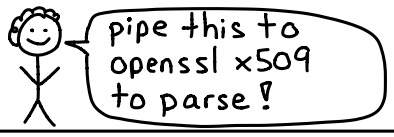
inspect a certificate

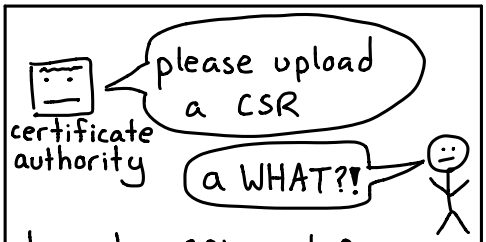
```
$ openssl x509 -in
  FILE.crt -noout -text
```

this works for files ending in .crt or .pem! Try it out: you probably have certs in /usr/share/ca-certificates

look at a website's certificate

```
$ openssl s_client
  -showcerts -connect
  google.com:443
```





to get a SSL cert for your website, you need to make a file called a "certificate signing request".

make a CSR

```
$ openssl req -new
  -sha256  -key FILE.key
  -out FILE.csr
```

make one of these with `$ openssl genrsa`

md5 / sha1 / sha256 / sha512

Not quite SSL but useful:

```
$ openssl md5 FILE
```

computes the md5sum of FILE. Same for other digests

```
$ openssl list -digest-commands
```

shows all supported digests.

BPF cheat sheet

Berkeley Packet Filter

a small language you can use to filter which packets tcpdump and ngrep capture

Use it like this:

```
$ tcpdump [your bpf here]
$ ngrep [your bpf here]
```

host

Filter based on the source or destination IP address

```
src host google.com   (use domain or IP)
dst host 192.168.1.1
host 127.0.0.1
```

same as "src or dst host"

port

```
src port 53
port 80
```

again, same as "src or dst port"

less / greater

Packet length!

```
less 80
greater 200
```

and / or / not

```
host 127.0.0.1 and port 80

udp and port 53

(port 53 or port 99) and
 not host 127.0.0.1
```

PROTOCOL[INDEX]

filter based on a specific byte in a packet

IP packets with options:

```
ip[0] & 0xF == 5   (bitwise and)
```

DNS SERVFAIL responses:

```
udp[11] & 0xF > 0
```

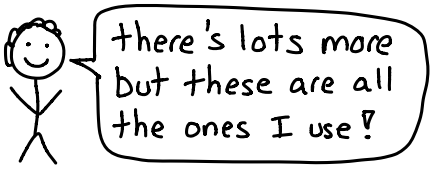
SYN packets:

```
tcp[tcpflags] == tcp-syn
```

tcp / udp / icmp

IPv4→ip / ip6

only show packets using that protocol



tshark

♥ Wireshark ♥ is an amazing graphical packet analysis tool

tshark is the command line version of Wireshark

it can do 100x more things than tcpdump ♥

-Y

filter which packets are captured

```
tshark -Y
'http.request.method == "GET"'
```

↑ uses Wireshark's SUPER POWERFUL filter language

-d

is for "decode as"

tells tshark what protocol to interpret a port as

Example: 8888 is often HTTP!

```
$ tshark
  -d tcp.port==8888,http
```

-T FORMAT

Output format. My favourites:

- ★json
- ★fields: csv/tsv } for these you can specify which fields you want with -e
- ★text: default summary

-e

Which fields to output. Ex:

```
$ tshark -T fields
  -e http.request.method
  -e http.request.uri
  -e ip.dst
```

↖ supports WAY more protocols than HTTP

```
GET /foo 92.183.216.34
POST /bar 10.23.38.132
```

-r file.pcap

analyze packets from a file instead of the network

-w

← same as tcpdump's

Write captured packets to a file. If -w file.pcap has permission issues, try:

```
tshark -w - > file.pcap
```

ngrep

like grep for your network

```
$ sudo ngrep GET
```

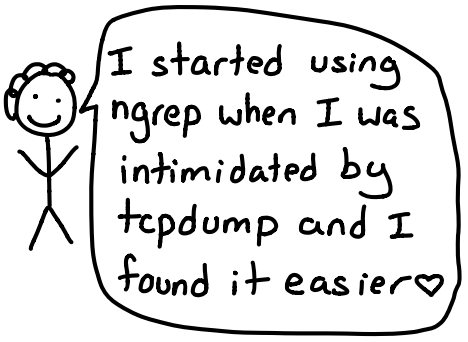
will find every plaintext HTTP GET request

ngrep syntax

```
$ ngrep
  [options]
  [regular expression]
  [BPF filter]
```

what to search packets for ↓

↑ same format as tcpdump uses!



-d

is for device

which network interface to use. same as tcpdump's (try '-d any'!)

-W byline

prints line breaks as line breaks, not "\n". Nice when looking at HTTP requests

-I file.pcap
-O file.pcap

read/write packets from/to a pcap file
